App modernization / Serverless App hands-on lab

Abstract and learning objectives

Explore the options for serverless architectures.

Learning Objectives:

- Implement a simple HTTP Endpoint using Azure Functions
- Utilize Azure Service Bus as messaging middleware
- Explore the possibilities of Azure Logic Apps to integrate with 3rd party applications

Solution architecture

After lawyers affirmed that Contoso Ltd. could legally process and store customer data in the cloud, Contoso created a strategy that capitalized on the capabilities of Microsoft Azure.

The existing solution is a Web Service accepting update notifications on new cases. Relying parties have been reporting issues with the performance of the service. Investigation exposed the synchronous integration pattern was not a perfect solution for the given amount of connected services.

The new solution should leverage serverless application architecture as much as possible. The API should accept the message and initiate the processing steps asynchronously. It must also be able to adjust to higher load of notifications.

API endpoint will be implemented as Azure Function. Messages requiring further processing will be put in a queue from where they will be picked by a Logic App, which in turn will handle the communication with 3rd party applications.

Requirements

To complete this lab, you will only need a browser (Microsoft Edge or Google Chrome recommended)

Before the hands-on lab

Duration: 5 minutes

Please make sure that you have access to the Azure Portal and either have permissions to create new Resource Groups or you have been provided a dedicated Resource Group where you can create Azure Assets.

Create a resource group

[Basics](#) [Tags](#) [Review + create](#)

Resource group - A container that holds related resources for an Azure solution. The resource group can include all the resources for the solution, or only those resources that you want to manage as a group. You decide how you want to allocate resources to resource groups based on what makes the most sense for your organization. [Learn more](#)

Exercise 1: Provision and execute a Function App

Duration: 20 minutes

The company has asked you to provision a simple API to process incoming events. As a Node.js developer, you prefer to keep using this stack for development.

Task 1: Create a new Function App

Tasks to complete

1. Locate the **Function App** template in the available Azure Resources and click on **Create**.
2. Provide basic information for the new Function App. Make sure you selected the Resource Group you plan to use for this exercise. Select Node.js as Runtime stack.

Function App

 Looking for the classic Function App create experience? →

[Basics](#) [Hosting](#) [Monitoring](#) [Tags](#) [Review + create](#)

Create a function app, which lets you group functions as a logical unit for easier management, deployment and sharing of resources. Functions lets you execute your code in a serverless environment without having to first create a VM or publish a web application.

Project Details

Select a subscription to manage deployed resources and costs. Use resource groups like folders to organize and manage all your resources.

Plan type *  

4. Leave the remaining settings unchanged, review the settings and start creation of the Resource. Wait until the Function App is successfully provisioned.

Exit criteria

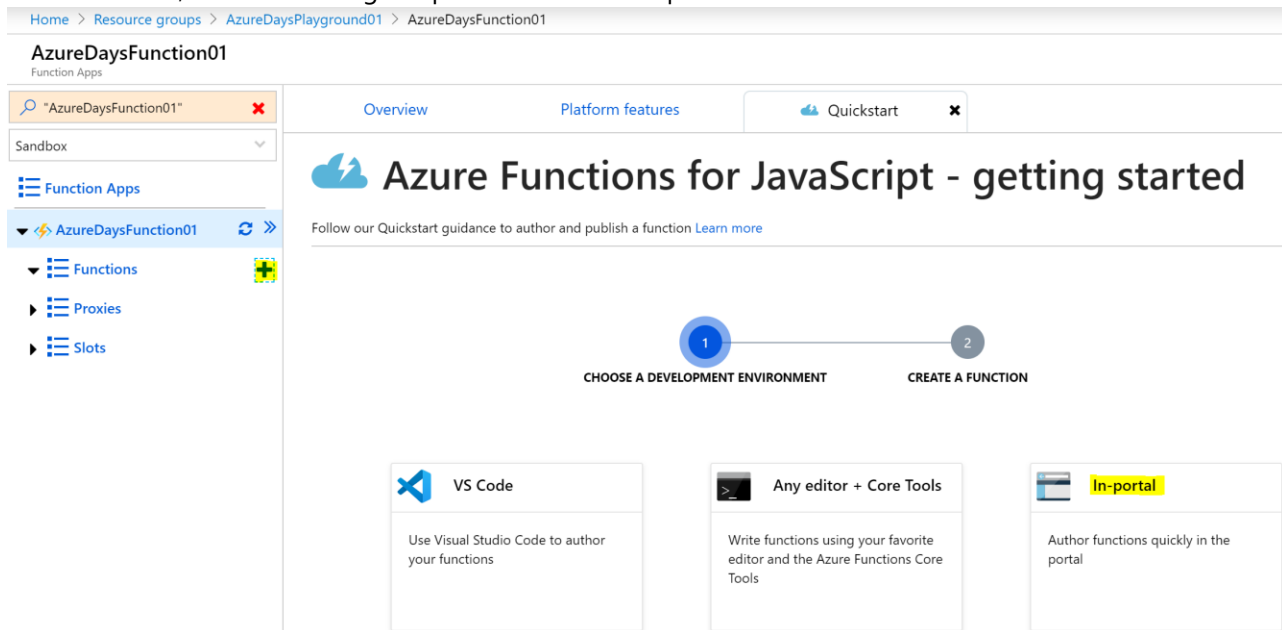

- Function App is successfully provisioned in the dedicated Resource Group

Task 2: Create and a new Function

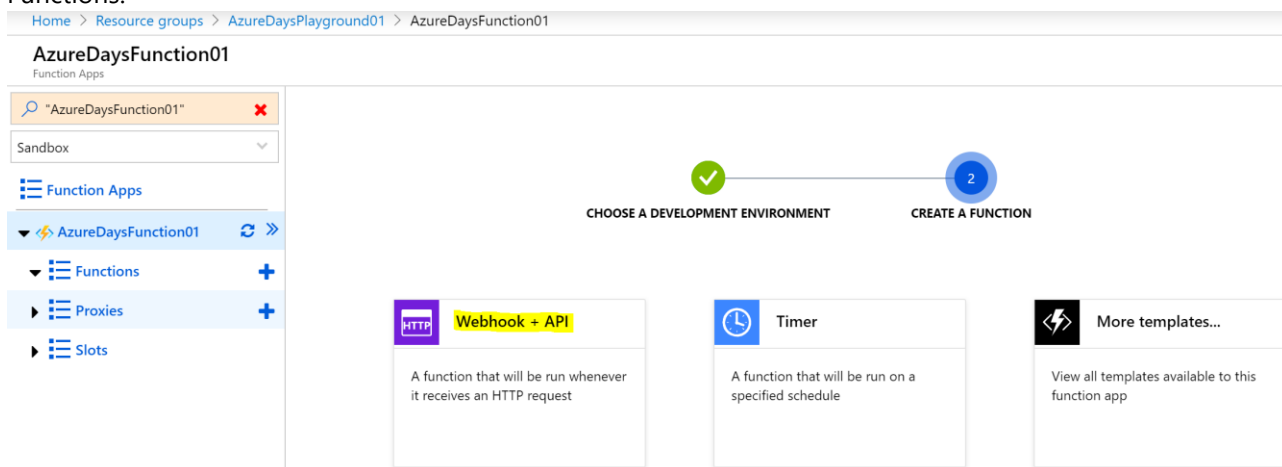

Tasks to complete

1. Locate and open the new Function App in the dedicated Resource Group.

- From here you can create a new Function by clicking on the “+” Button next to Functions menu entry. In this exercise, we will be using the portal as our development environment.

- We will be using an HTTP(s) endpoint as a trigger for our function. Feel free to explore other options for triggering Functions.

- The newly created function exposes some basic functionality. Explore the source code of the app (index.js) and identify how the HTTP input is being processed.
- Execute the Function using the portal testing facilities, analyze the output.
- Retrieve the Function URL and call it directly in your browser.
- Inspect the call history in the Monitor section of the function.

Exit criteria

- Webhook / API Function is successfully created
- Function can be successfully executed with different values of parameter in the portal and by calling a URL in browser
- Run history is recorded and visible in the Monitoring section

Exercise 2: Deploy and utilize messaging middleware

Duration: 20 minutes

Some messages received via the newly created API will need to be processed asynchronously. You need to provide a way to enable deferred processing of such messages.

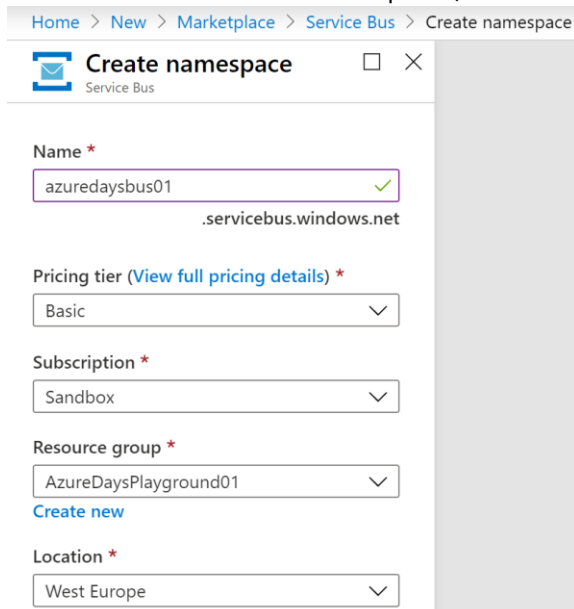

Help references

Azure Functions Service Bus Bindings	https://docs.microsoft.com/en-us/azure/azure-functions/functions-bindings-service-bus
--------------------------------------	---

Task 1: Create a message queue

Tasks to complete

1. Create a new Service Bus Namespace (Basic Pricing Tier is sufficient for the purpose of the given exercise)

The screenshot shows the 'Create namespace' form in the Azure Portal. The breadcrumb navigation at the top reads: Home > New > Marketplace > Service Bus > Create namespace. The form has a title 'Create namespace' with a Service Bus icon and a close button. It contains several fields: 'Name' with the value 'azuredaysbus01' and a green checkmark, followed by '.servicebus.windows.net'; 'Pricing tier (View full pricing details)' with a dropdown set to 'Basic'; 'Subscription' with a dropdown set to 'Sandbox'; 'Resource group' with a dropdown set to 'AzureDaysPlayground01' and a 'Create new' link below it; and 'Location' with a dropdown set to 'West Europe'.

2. In the newly created namespace, create a new Queue named **outqueue** with standard settings.

Exit criteria

- Service Bus Namespace and Queue are provisioned and visible in the dedicated Resource Group.

Task 2: Integrate Service Bus Queue with Function

Tasks to complete

1. Return to the Function App in Azure Portal, select the Http Trigger Function and click on **Integrate**. Explore the 3 different binding types: Trigger, Input and Output.

2. Add a new Output of type **Azure Service Bus**. Follow the suggestion to install the required extension – it may take a few minutes to complete.

Azure Service Bus output

3. Verify the settings of the binding, ensure that the **Message type** is set to "Service Bus Queue".

Azure Service Bus output [✕ delete](#)

Extension Installation Succeeded

Message type ⓘ
Service Bus Queue

Service Bus connection ⓘ [show value](#)
azuredaysbus01_RootManageSharedAccessKey_SE [new](#)

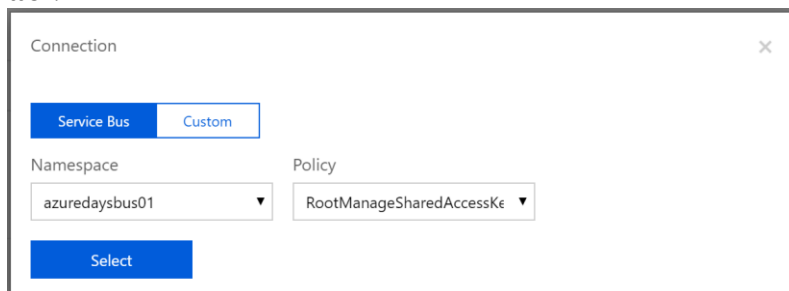

Message parameter name ⓘ
outputSbMsg

Queue name ⓘ
outqueue

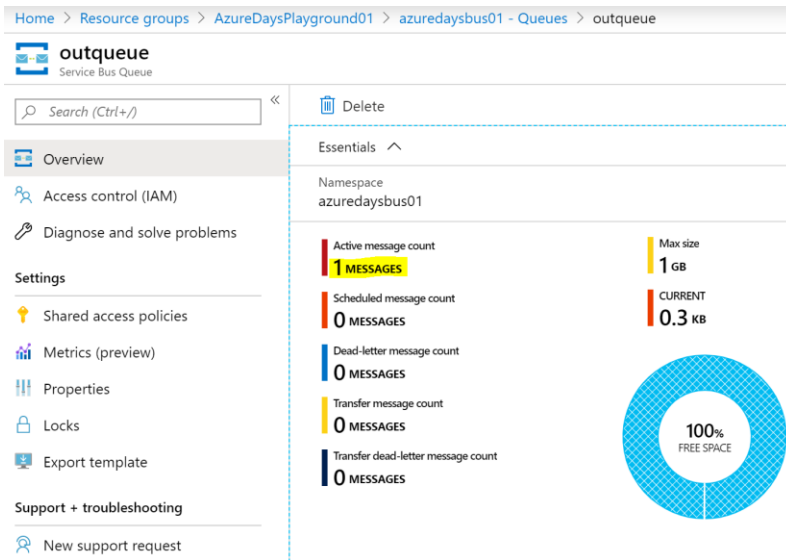

☐ Use function return value

[Save](#) [Cancel](#)

For Service bus connection, click on "new" and select the service bus namespace you provisioned in the previous task.

4. Save the binding settings.
5. The new binding is exposed via `context.bindings.outputSbMsg`. Assigning a text value to the property will result in sending a message to the configured queue after the function is executed. Add a line such as `context.bindings.outputSbMsg = (req.query.name || req.body.name) + " was here";` to the function body. Please refer to the official documentation for details.
6. Execute the function either via portal test or by calling the function-related URL in the browser.
7. Switch to the service bus queue in the portal. A dashboard displayed in the queue overview should indicate that the queue contains active messages.

Exit criteria

- Service Bus binding is configured for the new function, dependencies are successfully installed.
- Function execution sends messages to the queue.

Exercise 3: Process messages using a Logic App

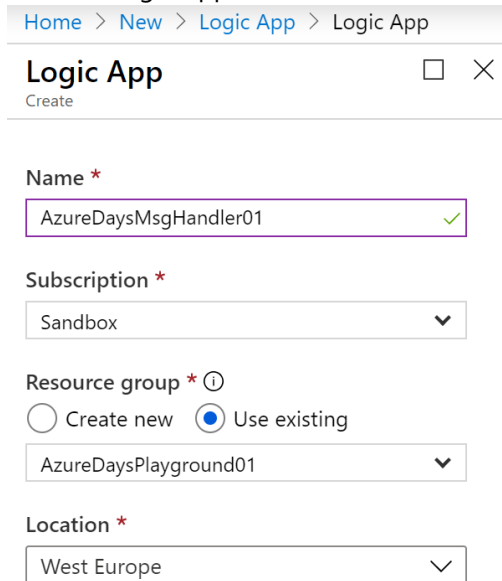

Duration: 20 minutes

Azure Logic Apps' wide range of supported connectors make it a perfect candidate for scenarios where integration with various Line of Business and Productivity applications is required. In this exercise we will trigger a Logic App to send an Email directly to O365 Outlook Mailbox.

Task 1: Create a message handler Logic App

Tasks to complete

1. Create a Logic App in the Azure Portal

Home > New > Logic App > Logic App

Logic App Create

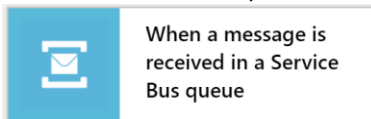

Name *

Subscription *

Resource group * ☐ Create new ☒ Use existing

Location *

2. Select a Service Bus queue as a trigger

3. In the new Logic App, configure the service bus connection by selecting the Service Bus namespace and the Queue name. Also set the polling interval to 1 Minute.

Service Bus

* Connection Name: Ingress

* Service Bus Namespace:

Name	Resource Group	Location
azuredaysbus01	AzureDaysPlayground01	West Europe

When a message is received in a queue (auto-complete)

* Queue name: Name of the queue

Queue type: outqueue

How often do you want to check for items?

* Interval: 1

* Frequency: Minute

4. Add a new action of type Send an Email (V2). Configure a personal connection to O365 Outlook. Explore how the output blocks of the previous steps is made available in the subsequent steps of the workflow via dynamic content: add the content of the message to the email body, experiment with expressions, there's a lot to discover.

Send an email (V2)

* To: magro@microsoft.com

* Subject: Message id [dynamic content icon] Message Id x

* Body: [Rich text editor with 'Content x' inserted]

Add dynamic content +

- Content**
Content of the message
- Content Type**
Content type of the message content
- Correlation Id**
Identifier of the correlation

5. After saving the workflow it automatically starts listening to the trigger events and runs when messages arrive in the queue.

Exit criteria

- Message handler Logic App listening to the Service Bus queue is created and deployed.

Task 2: Test the application

Your first application spanning a lightweight HTTP Handler, a messaging middleware and a message processor is now complete and ready to be tested.

Tasks to complete

1. Submit a message to the Function URL.
2. Open the Monitor tab of your Function and inspect the record.
3. Wait until the Logic App is executed
4. Explore the run history of the Logic App, identify the most recent run. Inspect the inputs and outputs of the actions.

Exit criteria

- Your application is performing as expected
- You can identify the building blocks and understand how they work in combination

Exercise 3 (optional): Build your own app

Duration: 30 minutes

Feel free to suggest your own scenario and try to implement it. Explore additional opportunities for integration.
